Brief Project Overview

Take an existing particle simulation toolkit - Geant4 - and have some functions run on a GPU device to improve performance.

What is Geant4?

- Geant4 is a toolkit that is meant to simulate the passage of particles through matter.
- It has been developed over the years through collaborative effort of many different institutions and individuals.
- Geant4's diverse particle simulation library has a wide variety of applications including
 - High energy physics simulations
 - Space and radiation simulations
 - Medical physics simulations

Demonstration

Demonstration – Running Geant4 on the CPU Hadr04 With Visualization

What is GP-GPU Computing?

- General-purpose graphic-processing-unit computing is a re-purposing of graphics hardware
- Allows GPUs to perform computations that would typically be computed on the CPU
- If a particular problem is well suited to parallelization, GP-GPU computing can greatly increase performance

Scope

- Make current CPU functions available for use on GPU
 - Add appropriate prefixes to function definitions
 - Make use of multiple parallel threads to execute each function
- Ensure correctness of each GPU available function by matching results to the corresponding CPU function
- Compare performance of GPU available functions to CPU functions

Purpose

- Determine if target functions are suitable to parallelization
- Increase performance of functions when run on GPU
- Decrease time required to run simulations involving ported functions

Features

- GPU acceleration available on an “opt-in” basis
- Easy to enable/disable GPU acceleration
- If GPU acceleration is enabled, some methods will run on GPU
- Same results whether acceleration enabled or disabled

Easily Enable/Disable GPU Acceleration

- Existing projects can use GPU acceleration without having to change any code
- Flag during build phase enables/disables GPU acceleration
- No new functions to learn ¹

¹implementation 1 only

Demonstration

Demonstration – Enabling CUDA Acceleration

Easily Enable/Disable GPU Acceleration

Method calls to G4ParticleHPVector forwarded to GPU-based implementation

- This decision is made at compile time based on cmake flag

Example of Forwarding Method Calls

```
inline G4double GetY(G4double x)
{
    #if GEANT4_ENABLE_CUDA
        return cudaVector->GetXsec(x);
    #else
        return GetXsec(x);
    #endif
}
```

Accelerating Module on GPU

Existing module G4ParticleHPVector ported to GPU using CUDA

Definition: CUDA

CUDA is a GP-GPU programming model developed by NVIDIA, for use with NVIDIA graphics cards

Why G4ParticleHPVector?

- Represents empirically-found probabilities of collisions for different particles based on their energy
- Identified as starting point by relevant stakeholders
 - Used heavily in simulations run by stakeholders
- Seems well-suited to parallelization
 - Based on large vector of 2D points
 - Performs calculations over this vector
 - Sorted by x-value (particle energy)

Two Implementations

- 1 Forward all calls to existing G4ParticleHPVector interface to a GPU-based implementation of the module
 - Store data vector in GPU memory
 - Copy results back to the CPU to return to the caller
- 2 Add new methods to G4ParticleHPVector interface that are well-suited to GPU computing
 - Copy data vector to GPU memory on method call
 - Existing G4ParticleHPVector methods unchanged, continue to run on CPU

Impl. 1: Existing Module in GPU Memory

Calls to `G4ParticleHPVector` forwarded to new GPU-based class

Pros:

- + Do not have to maintain a copy of the vector on the CPU
- + Do not have to maintain a hashed vector
- + Reduces how much is being copied to the GPU

Cons:

- All methods are run on the GPU

Demonstration

Hadr04 with Visualization

Impl. 1 – Times

Impl. 1 – GetXSec

Impl. 1: Performance Results Summary

- Most methods slower on GPU until ~10,000 entries in data vector
- Most *commonly-used* methods significantly slower on GPU, even with large data vector
 - Lots of data accesses
- Many problems in vector class not well-suited to parallelism

Impl. 1: Performance Results – Times

- Multiplies each point in vector by factor

Figure: Runtime vs. Number of Data Points – Times

Impl. 1: Performance Results – GetXSec

Figure: Runtime vs. Number of Data Points – GetXSec

Impl. 1: Performance Results – SampleLin

Figure: Runtime vs. Number of Data Points – SampleLin

Impl. 1: Performance Results – System Tests

Impl. 1: Performance Discussion

Impl. 2: Add New GPU-Accelerated Methods to Interface

Add new methods to G4ParticleHPVector interface that are well-suited to parallelism

Pros:

- + Only methods that run faster on the GPU are implemented
- + Not forced to run methods that run slowly on GPU

Cons:

- Will have to maintain two copies of the vector
- More copying the vector to and from the GPU

Impl. 2: GetXSecList

- Fill an array of energies for which we want to cross section values
- Send the array to the GPU to work on
- Each thread work on its own query(s)

Impl. 2: Performance Results Summary

Impl. 2: Performance Results – GetXSecList

Impl. 2: Performance Results – System Tests

Impl. 2: Performance Discussion

Accuracy

- All modified functions except SampleLin and Sample yield results that precisely match
- Some functions fell extremely close in accuracy to the original, and were considered to 'pass'
- The average of 1000 SampleLin tests deviated from the average of 1000 tests of the original with an error of 0.01
- The system tests differ if the number of nentries is greater than 500; if not however the results of the system test conform.

Accuracy

- The deviations in SampleLin and Sample can be attributed to the functions use of random numbers
- The negligible deviations in other ported functions are likely attributed to differences in CPU and GPU arithmetic, leading to different round-off errors

Testing

- Comparing test results and performance with GPU acceleration enabled and disabled
- Testing framework based on two phases, one program for each phase
 - 1 `GenerateTestResults`: Run unit tests and save results to file
 - 2 `AnalyzeTestResults`: Compare results from CPU and GPU
- Run `GenerateTestResults` once for GPU acceleration enabled, once with it disabled

GenerateTestResults Details

- Includes testing version number in results file for analysis stage
- Outputs simple results directly to results file
- For vectors, calculates hash for vector and output it
- Outputs timing data to separate file

Example: Snippet of Generated Test Results

```
#void G4ParticleHPVector_CUDA::GetXsecBuffer(  
    G4double * queryList, G4int length)_6  
@numQueries=10  
hash: 16548307878283220284  
@numQueries=50  
hash: 3204132713354913775
```

Demonstration

Demonstration – Generating Test Results

AnalyzeTestResults Details

Two main functions:

- 1 Compare results for each test case, printing status to stdout
 - If test failed, output differing values
 - Summarize test results at the end with number passed
- 2 Generate .csv file from timing data
 - One row per unique method call, columns show CPU time, GPU time, method name and parameters
 - Can use Excel to analyze performance results
